Chapter 01.06
Propagation of Errors

If a calculation is made with numbers that are not exact, then the calculation itself will have an error. How do the errors in each individual number propagate through the calculations. Let’s look at the concept via some examples.

Example 1

Find the bounds for the propagation error in adding two numbers. For example if one is calculating $Y + X$ where

$X = 1.5 \pm 0.05,$

$Y = 3.4 \pm 0.04.$

Solution

By looking at the numbers, the maximum possible value of $X$ and $Y$ are

$X = 1.55$ and $Y = 3.44$

Hence

$X + Y = 1.55 + 3.44 = 4.99$

is the maximum value of $X + Y$.

The minimum possible value of $X$ and $Y$ are

$X = 1.45$ and $Y = 3.36$.

Hence

$X + Y = 1.45 + 3.36$

$= 4.81$

is the minimum value of $X + Y$.

Hence

$4.81 \leq X + Y \leq 4.99.$

One can find similar intervals of the bound for the other arithmetic operations of $X - Y, X \times Y, and X / Y$. What if the evaluations we are making are function evaluations instead? How do we find the value of the propagation error in such cases?

If $f$ is a function of several variables $X_1, X_2, X_3, ..., X_{n-1}, X_n$, then the maximum possible value of the error in $f$ is

$$\Delta f \approx \left| \frac{\partial f}{\partial X_1} \Delta X_1 \right| + \left| \frac{\partial f}{\partial X_2} \Delta X_2 \right| + \ldots + \left| \frac{\partial f}{\partial X_{n-1}} \Delta X_{n-1} \right| + \left| \frac{\partial f}{\partial X_n} \Delta X_n \right|$$
Example 2
The strain in an axial member of a square cross-section is given by
\[ \varepsilon = \frac{F}{h^2E} \]
where
\[ F = \text{axial force in the member, N} \]
\[ h = \text{length or width of the cross-section, m} \]
\[ E = \text{Young's modulus, Pa} \]

Given
\[ F = 72 \pm 0.9 \text{ N} \]
\[ h = 4 \pm 0.1 \text{ mm} \]
\[ E = 70 \pm 1.5 \text{ GPa} \]

Find the maximum possible error in the measured strain.

Solution
\[ \varepsilon = \frac{72}{(4 \times 10^{-3})^2 (70 \times 10^9)} \]
\[ = 64.286 \times 10^{-6} \]
\[ = 64.286 \mu \]

\[ \Delta \varepsilon = \left| \frac{\partial \varepsilon}{\partial F} \Delta F \right| + \left| \frac{\partial \varepsilon}{\partial h} \Delta h \right| + \left| \frac{\partial \varepsilon}{\partial E} \Delta E \right| \]

\[ \frac{\partial \varepsilon}{\partial F} = \frac{1}{h^2E} \]
\[ \frac{\partial \varepsilon}{\partial h} = -\frac{2F}{h^3E} \]
\[ \frac{\partial \varepsilon}{\partial E} = -\frac{F}{h^2E^2} \]

\[ \Delta E = \left| \frac{1}{h^2E} \Delta F \right| + \left| -\frac{2F}{h^3E} \Delta h \right| + \left| -\frac{F}{h^2E^2} \Delta E \right| \]
\[ = \left| \frac{1}{(4 \times 10^{-3})^2 (70 \times 10^9)} \times 0.9 \right| + \left| -\frac{2 \times 72}{(4 \times 10^{-3})^3 (70 \times 10^9)} \times 0.001 \right| \]
\[ + \left| -\frac{72}{(4 \times 10^{-3})^2 (70 \times 10^9)} \times 1.5 \times 10^9 \right| \]
\[ = 8.0357 \times 10^{-7} + 3.2143 \times 10^{-6} + 1.3776 \times 10^{-6} \]
\[ = 5.3955 \times 10^{-6} \]
\[ = 5.3955 \mu \]

Hence
\[ \varepsilon = (64.286 \mu \pm 5.3955 \mu) \]

implying that the axial strain, \( \varepsilon \) is between \( 58.8905 \mu \) and \( 69.6815 \mu \)
Example 3

Subtraction of numbers that are nearly equal can create unwanted inaccuracies. Using the formula for error propagation, show that this is true.

Solution

Let

\[ z = x - y \]

Then

\[
|\Delta z| = \left| \frac{\partial z}{\partial x} \Delta x + \frac{\partial z}{\partial y} \Delta y \right|
\]

\[
= \left| (1)\Delta x + (-1)\Delta y \right|
\]

\[
= |\Delta x| + |\Delta y|
\]

So the absolute relative change is

\[
\left| \frac{\Delta z}{z} \right| = \left| \frac{\Delta x}{x} + \frac{\Delta y}{y} \right|
\]

As \( x \) and \( y \) become close to each other, the denominator becomes small and hence create large relative errors.

For example if

\[
x = 2 \pm 0.001
\]

\[
y = 2.003 \pm 0.001
\]

\[
\left| \frac{\Delta z}{z} \right| = \left| \frac{0.001}{2} + \frac{0.001}{2.003} \right|
\]

\[
= 0.6667
\]

\[
= 66.67\%
\]
