

Differentiation of Continuous Functions

Central Difference Approximation of the First Derivative

Ana Catalina Torres, Autar Kaw

University of South Florida

United States of America

kaw@eng.usf.edu

▼ Introduction

This worksheet demonstrates the use of Maple to illustrate Central Difference Approximation of the first derivative of continuous functions.

Central Difference Approximation of the first derivative uses a point h ahead and a point h behind of the given value of x at which the derivative of $f(x)$ is to be found.

$$f'(x) \approx \frac{f(x+h) - f(x-h)}{2 \cdot h}$$

▼ Initialization

```
> restart;  
with (plots) :
```

▼ Section 1: Input

The following simulation approximates the first derivative of a function using Central Difference Approximation. The user inputs are

- function, $f(x)$
- point at which the derivative is to be found, xv
- starting step size, h
- number of times user wants to halve the step size, n

The outputs include

- approximate value of the derivative at the point and given initial step size
- exact value
- true error, absolute relative true error, approximate error and absolute relative approximate error, number of at least correct significant digits in the solution as a function of step size.

```
Function  $f(x)$ .
```

```
> f := x → exp(2·x);
```

$$f := x \rightarrow e^{2x}$$

(3.1)

```
Value of  $x$  at which  $f'(x)$  is desired,  $xv$ 
```

```
> xv := 4.0;
```

```

Starting step size,  $h$ 

```

$$xv := 4.0 \tag{3.2}$$

```

>  $h := 0.2;$ 

```

$$h := 0.2 \tag{3.3}$$

```

Number of times step size is halved
>  $n := 6;$ 

```

$$n := 6 \tag{3.4}$$

This is the end of the user section. All the information must be entered before proceeding to the next section. Re-execute the program.

Section 2: Procedure

The following procedure estimates the solution of first derivative of an equation at a point xv .

$f(x)$ = function

xv = value at which the solution is desired

h = step size value

n = number of times step size is halved

```

>  $CDD := \text{proc}(f, xv, h)$ 
   $\text{local deriv} :$ 
   $\text{deriv} := \frac{(f(xv + h) - f(xv - h))}{2 \cdot h} ;$ 
   $\text{return}(deriv) ;$ 
 $\text{end proc} ;$ 

```

Section 3: Calculation

The exact value Ev of the first derivative of the equation:

First, using the *diff* command the solution is found. In a second step, the exact value of the derivative is shown.

```

>  $y(x) = f(x);$ 

```

$$y(x) = e^{2x} \tag{5.1}$$

```

>  $Soln := \text{diff}(f(x), x);$ 

```

$$Soln := 2 e^{2x} \tag{5.2}$$

```

>  $Ev := \text{evalf}(\text{subs}(x = xv, Soln));$ 

```

$$Ev := 5961.915974 \tag{5.3}$$

The next loop calculates the following:

Av: Approximate value of the first derivative using Central Difference Approximation by calling the procedure "CDD"

Ev: Exact value of the first derivative

Et: True Error

et: Absolute relative true percentage error

Ea: Approximate Error

ea: Absolute relative approximate percentage error

Sig: Least number of correct significant digits in an approximation

```

>  $\text{for } i \text{ from } 0 \text{ by } 1 \text{ to } n - 1 \text{ do}$ 

```

```

N[i] := 2i :
H[i] :=  $\frac{h}{N[i]}$  :
Av[i] := CDD(f, xv, H[i]) :
Et[i] := Ev - Av[i] :
et[i] := abs( $\frac{Et[i]}{Ev}$ ) · 100 :
  if (i > 0) then
    Ea[i] := Av[i] - Av[i - 1] :
    ea[i] := abs( $\frac{Ea[i]}{Av[i]}$ ) · 100 :
    if (ea[i] > 0) then
      Sig[i] := floor( $2 - \log_{10}\left(\frac{ea[i]}{0.5}\right)$ ) :
      if Sig[i] < 0 then
        Sig[i] := 0 :
      end if:
    end if:
    if (ea[i] = 0) then
      Sig[i] := Digits :
    end if:
  end if:
end do:

```

The loop halves the value of the step size n times. Each time, the approximate value of the derivative is calculated and saved in a vector. The approximate error is calculated after at least two approximate values of the derivative have been saved. The number of significant digits is calculated and written as the lowest real number. If the number of significant digits calculated is less than zero, then is shown as zero.

Section 4: Spreadsheet

The next table shows the step size value, approximate value, true error, the absolute relative true percentage error, the approximate error, the absolute relative approximate percentage error and the least number of correct significant digits in an approximation as a function of the step size value.

```

> with(Spread) :
  tableoutput := CreateSpreadsheet("Central Divided Difference") :
  SetCellFormula(tableoutput, 1, 2, "Step Size") :
  SetCellFormula(tableoutput, 1, 3, "Approx Value") :
  SetCellFormula(tableoutput, 1, 4, "True Error") :
  SetCellFormula(tableoutput, 1, 5, "Abs Rel True Error") :
  SetCellFormula(tableoutput, 1, 6, "Approx error") :
  SetCellFormula(tableoutput, 1, 7, "Abs Rel Approx Error") :
  SetCellFormula(tableoutput, 1, 8, "Sig Digits");

```

```

for i from 0 by 1 to n-1 do
  SetCellFormula(tableoutput, i+2, 1, i+1) :
  SetCellFormula(tableoutput, i+2, 2, evalf(H[i])) :
  SetCellFormula(tableoutput, i+2, 3, evalf(Av[i])) :
  SetCellFormula(tableoutput, i+2, 4, evalf(Et[i])) :
  SetCellFormula(tableoutput, i+2, 5, evalf(et[i])) :
  SetCellFormula(tableoutput, i+2, 6, evalf(Ea[i])) :
  SetCellFormula(tableoutput, i+2, 7, evalf(ea[i])) :
  SetCellFormula(tableoutput, i+2, 8, evalf(Sig[i]));
end do:
EvaluateSpreadsheet(tableoutput) :

```

Questions

1. The velocity of a rocket is given by

$$v(t) = 2000 \cdot \ln \frac{140000}{140000 - 2100 t} - 9.8 t$$

Use Central Divided Difference method with a step size of 0.25 to find the acceleration at $t=5s$. Compare with the exact answer and study the effect of the step size.

2. Look at the true error vs. step size data for problem # 1. Do you see a relationship between the value of the true error and step size? Is this coincidental?

Conclusions

Central Difference Approximation is a very accurate method to find the first derivative of a function.
